Abstract
In this project an attempt is made to compare seismic analysis of water tanks using elastic analysis and p-Δ effect. The Circular and Intz type Water Tank are analyzed for critical load combination considering severe zone (V zone only). The analysis is to be carried out for Axial Force, Shear Force and Moments with p-Δ and without p-Δ conditions. In overall study of seismic analysis, critical load combination is found out. For these critical load combinations for different height like 16M, 20M, 24M various parameters are calculated. Important part of this project is to find out height wise variation in column displacement and column moment for same capacity of tank at different height of staging by taking same dimensions of bracing and column and significant co-relationship between these parameters are established.

Keywords- Elastic analysis, P-Δ analysis, STAAD-PRO Water Tank Model, Design of Water Tanks, seismic analysis results

I. INTRODUCTION

In India, elevated tanks are commonly used in the public water distribution systems. These elevated tanks are generally of reinforced cement concrete (RCC). Since these elevated tanks are integral parts of lifeline systems, their seismic safety is of considerable importance. During seismic response, lateral deformation increases very sharply causing p-Δ effect to play a very crucial role in the structures like elevated water tank, which has large mass concentration at the top and supported by a relative slender supporting system, seismic analysis of elevated tank needs special considerations.

A. Elastic Analysis
In the elastic range all steel elements and even the complete steel structure can be assumed to follow Hooke’s law and recover completely to their original state upon removal of load. The maximum elastic load capacity is determined when any point in any member section reaches the yield stress or elastic critical buckling stress where stability is a problem. Under a particular loading combination, the forces and moments throughout all or part of the structure may be determined by an analysis that assumes that individual members behave elastically.

B. P-Δ Analysis
[5] When a model is loaded, it deflects. The deflections in the members of the model may induce secondary moments due to the fact that the ends of the member may no longer be vertical in the deflected position. These secondary effects for members can be accurately approximated through the use of P-Delta analysis. This type of analysis is called “P-Delta analysis” because the magnitude of the secondary moment is equal to “P”, the axial force in the member, times “Δ”, the distance one end of the member is offset from the other end.

II. ANALYSIS AND DESIGN OF STRUCTURES

In this project Analysis and Design of Circular and Intz type of Tank of capacity 500m3 for different heights of staging like 16M, 20M and 24M for Critical Load combination 1.5DL + 1.5EL for zone V is done.

A. [1] Design Of Circular Water Tank and Intz Water Tank

Design of Water Tank container of capacity 500m³

By Conventional Method

2.1.1 [3] The Dimensions of the container of Circular Water Tank provided are

- Diameter of Tank - 13.5m
- Height of Tank - 3.8m
- Top Dome – 100mm thickness
- Bottom slab – 550mm depth
- Cylindrical Wall – 300mm thickness
- Top ring beam – 350mm x 350mm
- Bottom ring beam – 500mm x 800mm

The Dimensions of the container of Intz Water Tank provided are

- Diameter of Tank – 10m
- Top dome – 100mm thickness
- Top ring beam – 250mm x 250mm
- Circular side wall – 200mm thickness
- Bottom ring beam - 600mm x 600mm
- Conical dome – 600mm thickness
- Bottom spherical dome – 300mm thickness
- Bottom circular ring beam – 550mm depth

B. Design Of Supporting system using STAAD-PRO. IS 1893 (part 1): 2002

For 16m Height Of Column

1st Trial: Size of bracing: 0.3x0.3M
   Size of column: 0.3M diameter

2nd Trial: Size of bracing: 0.3x0.3M
   Size of column: 0.6M diameter

3rd Trial: Size of bracing: 0.3x0.3M
   Size of column: 0.55M diameter

4th Trial: Size of bracing: 0.3x0.3M
   Size of column: 0.4M diameter

Final dimensions For 16m, 20m, 24m Height Of Columns And Size Of Bracings: The following size of bracings and size of columns, the difference in axial force, shear force, moment for without p-delta and with p-delta condition for 16M height of staging in both case of Tanks is found. Hence for design and analysis purpose 20M and 24M height of staging of same dimensions of bracings and columns are carried out.

4th Trial: Size of bracing: 0.3x0.3M
   Size of column: 0.4M dia

IV. CONCLUSION

After considering p-delta effect it is observed that the end forces in bracing and columns are increased very marginally. The axial load is not equally distributed among the columns but it varies with its distance from the central axis. The sizes of column play an important role in redistributing the load carried by various columns. Maximum forces are carried by bracing provided at top panel. After application of earthquake force on tank and transferring it to staging, the forces in horizontal members are not increased. On other hand they are decreased in magnitude. As we increase the height of tank, p-delta effect is found to be more in 20M, 24M height of supporting system. Hence for this project study we can say that p-delta effect is directly proportional to height. Among the all two types of water tanks, intz tank is complicated in design and casting. But without p-delta and with p-delta for these both conditions, effect on Intz type of Tank as
compare to circular tank is less. Hence it is aesthetically good than circular
