### Abstract

Experiments were conducted to evaluate the performance of a high grade low heat rejection (LHR) diesel engine with air gap insulated piston, air gap insulated liner and ceramic coated cylinder head [ceramic coating of thickness 500 microns was done on inside portion of cylinder head] with different operating conditions [normal temperature and pre-heated temperature] of crude pongamia oil (CPO) with varied injection pressure and injection timing. Performance parameters of brake thermal efficiency, exhaust gas temperature and volumetric efficiency were determined at various magnitudes of brake mean effective pressure. Pollution levels of smoke and oxides of nitrogen (NOx) were recorded at the peak load operation of the engine. Combustion characteristics at peak load operation of the engine were measured with TDC (top dead centre) encoder, pressure transducer, console and special pressure-crank angle software package. Conventional engine (CE) showed deteriorated performance, while LHR engine showed improved performance with CPO operation at recommended injection timing and pressure and the performance of both version of the engine was improved with advanced injection timing and at higher injection pressure when compared with CE with pure diesel operation. The optimum injection timing was 32°bTDC for CE while it was 31°bTDC with LHR engine with vegetable oil operation. Peak brake thermal efficiency increased by 12%, smoke levels decreased by 6% and NOx levels increased by 41% with CPO operation on LHR engine at its optimum injection timing, when compared with pure diesel operation on CE at manufacturer's recommended injection timing of 27°bTDC. (Before top dead centre)

### Introduction

Diesel engines are the dominating one primarily in the field of transportation and

secondarily in agricultural machinery due to its superior fuel economy and higher fuel efficiency. The world survey explicit that the diesel fuel consumption is several times higher than that of gasoline fuel. These fuels are fossil in nature, leads to the depletion of fuel and increasing cost. It has been found that the vegetable oil is a promising fuel, because of their properties are similar to that of diesel fuel and it is a renewable and can be easily produced. Rudolph diesel, the inventor of the engine that bears his name, experimented with fuels ranging from powdered coal to peanut oil. Experiments were conducted [1-8] with CE with vegetable oils and blends of vegetable oil and diesel and reported that performance was deteriorated with CE. It is well known fact that about 30% of the energy supplied is lost through the coolant and the 30% is wasted through friction and other losses, thus leaving only 30% of energy utilization for useful purposes. In view of the above, the major thrust in engine research during the last one or two decades has been on development of LHR engines. Several methods adopted for achieving LHR to the coolant are i) using ceramic coatings on piston, liner and cylinder head ii) creating air gap in the piston and other components with low-thermal conductivity materials like supemi, cast iron and mild steel etc. Ceramic coatings provided adequate insulation and improved brake specific fuel consumption (BSFC) which was reported by various researchers. However previous studies [9-14] revealed that the thermal efficiency variation of LHR engine not only depended on the heat recovery system, but also depended on the engine configuration, operating condition and physical properties of the insulation material. Air gap was created in the nimonic piston crown [15] and experiments were conducted with pure diesel and reported that BSFC was increased by 7% with varied injection timings. Investigations were carried [16] with air gap insulated piston with supemi crown and air gap insulated liner with supemi insert with varied injection pressures and injection timings with alternate fuels of alcohols and vegetable oils and reported LHR engine improved efficiency and decreased pollution levels. Little

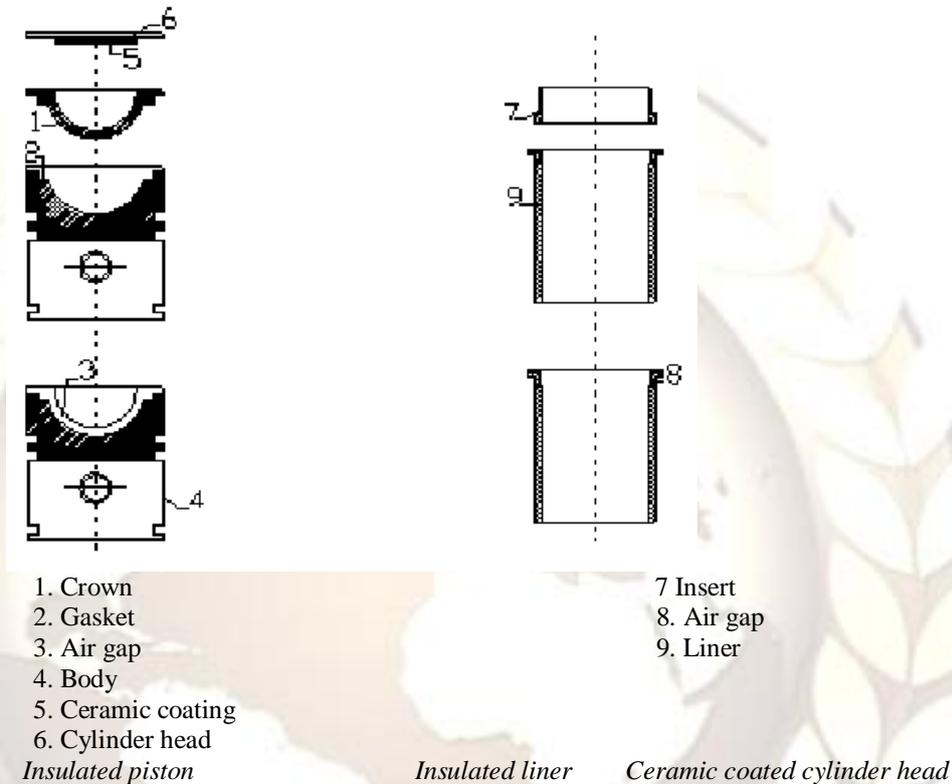

literature was available in evaluating the performance of LHR engine with air gap insulated piston and air gap insulated liner with ceramic coated cylinder head with varying engine parameters at different operating conditions of the vegetable oil. The present paper attempted to evaluate the performance of LHR engine, which contained an air gap insulated piston air gap insulated liner and ceramic coated cylinder head with different operating conditions of CPO with varying engine parameters of change of injection

pressure and timing and compared with CE at recommended injection timing and injection pressure.

### Experimental Programme

The properties of vegetable oil were taken from the Reference- 16.

Fig.1 gave the details of insulated piston, insulated liner and ceramic coated cylinder head employed in the experimentation.

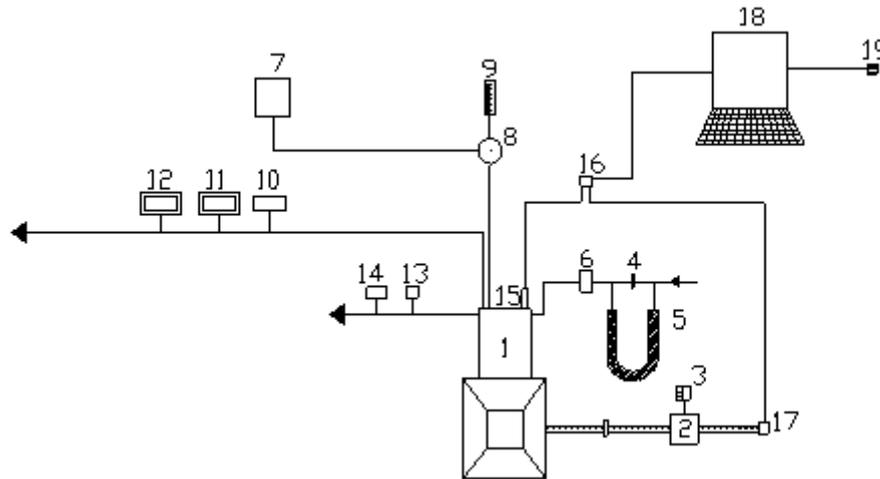

**Fig.1. Assembly details of insulated piston, insulated liner and ceramic coated cylinder head**

The low heat rejection diesel engine contained a two-part piston - the top crown made of low thermal conductivity material, superni-90 was screwed to aluminum body of the piston, providing a 3mm-air gap in between the crown and the body of the piston. The optimum thickness of air gap in the air gap piston was found to be 3-mm [15] for better performance of the engine with superni inserts with diesel as fuel. A superni-90 insert was

screwed to the top portion of the liner in such a manner that an air gap of 3-mm was maintained between the insert and the liner body. Partially stabilized zirconium (PSZ) of thickness 500 microns was coated on inside portion of cylinder head.

Experimental setup used for the investigations of LHR diesel engine with crude pongamia oil (CPO) was shown in Fig.2.

**Fig.2 Experimental Set-up**

CE had an aluminum alloy piston with a bore of 80-mm and a stroke of 110-mm. The rated output of the engine was 3.68 kW at a rate speed of 1500 rpm. The compression ratio was 16:1 and manufacturer's recommended injection timing and injection pressures were 27°bTDC and 190 bar respectively. The fuel injector had 3-holes of size 0.25-mm. The combustion chamber consisted of a direct injection type with no special arrangement for swirling motion of air. The engine was connected to electric dynamometer for measuring brake power of the engine. Burette method was used for finding fuel consumption of the engine. Air-consumption of the engine was measured by air-box method. The naturally aspirated engine was provided with water-cooling system in which inlet temperature of water was maintained at 60°C by adjusting the water flow rate. Engine oil was provided with a pressure feed system. No temperature control was incorporated, for measuring the lube oil temperature. Copper shims of suitable size were provided in between the pump body and the engine frame, to vary the injection timing and its effect on the performance of the engine was studied, along with the change of injection pressures from 190 bar to 270 bar (in steps of 40 bar) using nozzle testing device. The maximum injection pressure was restricted to 270 bar due to practical difficulties involved. Exhaust gas temperature (EGT) was measured with thermocouples made of iron and iron-constantan. Pollution levels of smoke and NO<sub>x</sub> were recorded by AVL smoke meter and Netel Chromatograph NO<sub>x</sub> analyzer respectively at the peak load operation of the engine. Piezo electric transducer, fitted on the cylinder head to measure pressure in the combustion chamber was connected to a

console, which in turn was connected to Pentium personal computer. TDC encoder provided at the extended shaft of the dynamometer was connected to the console to measure the crank angle of the engine.

A special P-θ software package evaluated the combustion characteristics such as peak pressure (PP), time of occurrence of peak pressure (TOPP), maximum rate of pressure rise (MRPR) and time of occurrence of maximum rate of pressure rise (TOMRPR) from the signals of pressure and crank angle at the peak load operation of the engine. Pressure-crank angle diagram was obtained on the screen of the personal computer

## Results and Discussion

### A. Performance Parameters

The variation of brake thermal efficiency (BTE) with brake mean effective pressure (BMEP) in the conventional engine (CE) with CPO, at various injection timings at an injection pressure of 190 bar, was shown in Fig.3. The variation of BTE with BMEP with pure diesel operation on CE at recommended injection timing was also shown for comparison purpose. CE with vegetable oil showed the deterioration in the performance for entire load range when compared with the pure diesel operation on CE at recommended injection timing. Although carbon accumulations on the nozzle tip might play a partial role for the general trends observed, the difference of viscosity between the diesel and vegetable oil provided a possible explanation for the deterioration in the performance of the engine with vegetable oil operation. In addition, less air entrainment by the fuel spray suggested that the fuel spray penetration might increase and resulted in more fuel reaching the

combustion chamber walls. Furthermore droplet mean diameters (expressed as Sauter mean) are larger for vegetable oil leading to reduce the rate of heat release as compared with diesel fuel. This also, contributed the higher ignition (chemical)

delay of the vegetable oil due to lower cetane number. According to the qualitative image of the combustion under the crude vegetable oil operation with CE, the lower BTE was attributed to the relatively retarded and lower heat release rates.

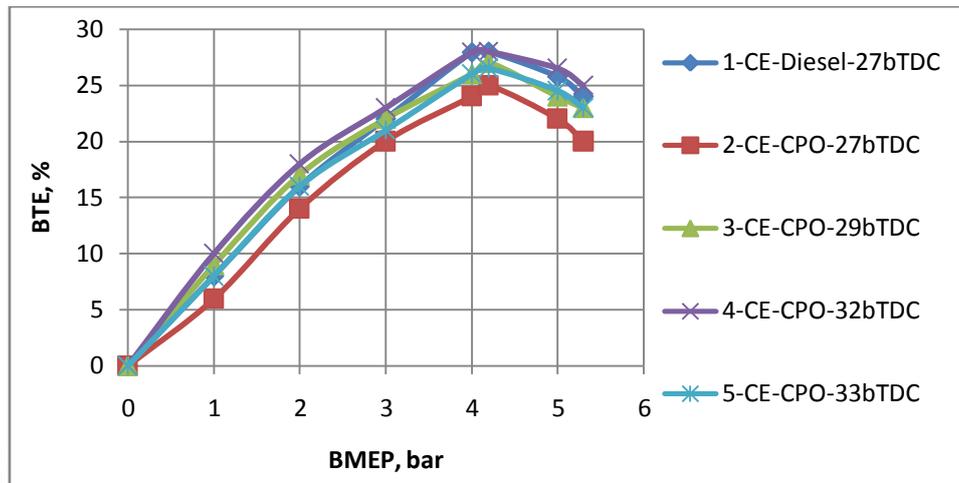

Fig.2 Variation of brake thermal efficiency (BTE) with brake mean effective pressure (BMEP) in conventional engine (CE) at different injection timings with crude pongamia oil (CPO) oil operation.

BTE increased with the advancing of the injection timing in CE with the vegetable oil at all loads, when compared with CE at the recommended injection timing and pressure. This was due to initiation of combustion at earlier period and efficient combustion with increase of air entrainment in fuel spray giving higher BTE. BTE increased at all loads when the injection timing was advanced to 32°bTDC in the CE at the normal temperature of vegetable oil. The increase of BTE at optimum injection timing over the recommended injection timing with vegetable oil with CE could be attributed to its longer ignition delay and

combustion duration. BTE increased at all loads when the injection timing was advanced to 32°bTDC in CE, at the preheated temperature of CPO. That, too, the performance improved further in CE with the preheated vegetable oil for entire load range when compared with normal vegetable oil. Preheating of the vegetable oil reduced the viscosity, which improved the spray characteristics of the oil and reduced the impingement of the fuel spray on combustion chamber walls, causing efficient combustion thus improving BTE.

The variation of BTE with BMEP in the LHR engine with CPO, at various injection timings at an injection pressure of 190 bar, was shown in Fig.4.

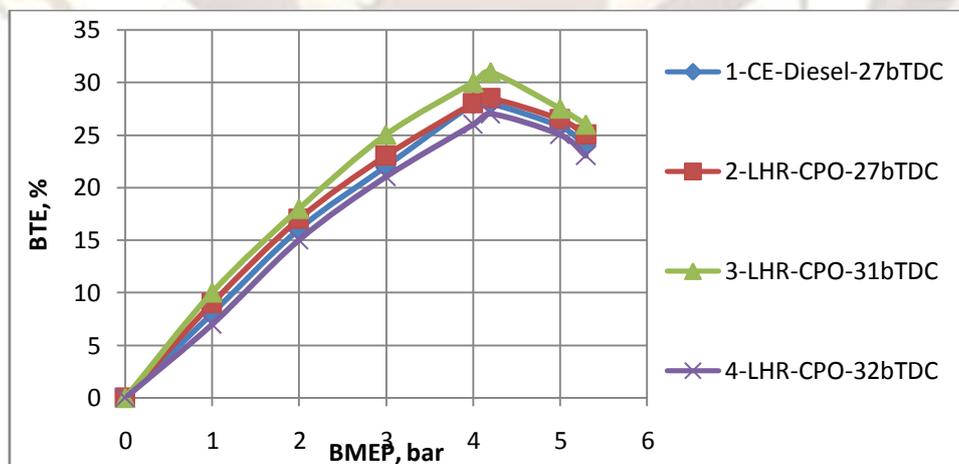

Fig.4 Variation of BTE with BMEP in LHR engine at different injection timings with crude pongamia oil operation (CPO).

LHR version of the engine showed the marginal improvement in the performance for entire load range compared with CE with pure diesel operation. High cylinder temperatures helped in better evaporation and faster combustion of the fuel injected into the combustion chamber. Reduction of ignition delay of the vegetable oil in the hot environment of the LHR engine improved heat release rates and efficient energy utilization. Preheating of vegetable oil improves performance further in LHR version of the engine. The optimum injection timing was found to be 31°bTDC with LHR engine with normal CPO. Since the hot combustion chamber of LHR engine reduced ignition delay and combustion duration and hence

the optimum injection timing was obtained earlier with LHR engine when compared with CE with the vegetable oil operation.

Injection pressure was varied from 190 bars to 270 bars to improve the spray characteristics and atomization of the vegetable oils and injection timing was advanced from 27 to 34°bTDC for CE and LHR engine. Table-1 showed the variation of BTE with injection pressure and injection timing at different operating conditions of CPO with different configurations of the engine. BTE increased with increase in injection pressure in both versions of the engine at different operating conditions of the vegetable oil.

DF-Diesel Fuel, CPO-Crude Pongamia Oil, NT- Normal or Room Temperature , PT- Preheat Temperature

The improvement in BTE at higher injection pressure was due to improved fuel spray characteristics. However, the optimum injection timing was not varied even at higher injection pressure with LHR engine, unlike the CE. Hence it was concluded that the optimum injection timing was 32°bTDC at 190 bar, 31°bTDC at 230 bar and 30°bTDC at 270 bar for CE. The optimum injection timing for LHR engine was 31°bTDC irrespective of injection pressure. Peak BTE was higher in LHR engine when compared with CE with different operating conditions of the vegetable oils.

Fig.5 showed the variation of the exhaust gas temperature (EGT) with BMEP in CE and LHR engine with CPO at normal temperature at the recommended and optimized injection timings at an injection pressure of 190 bar. CE with CPO at the recommended injection timing recorded higher EGT at all loads compared with CE with pure diesel operation. Lower heat release rates and retarded heat release associated with high specific energy consumption caused increase in EGT in CE. Ignition delay in the CE with different operating conditions of vegetable oil increased the duration of the burning phase. LHR engine recorded lower

value of EGT when compared with CE with vegetable oil operation.

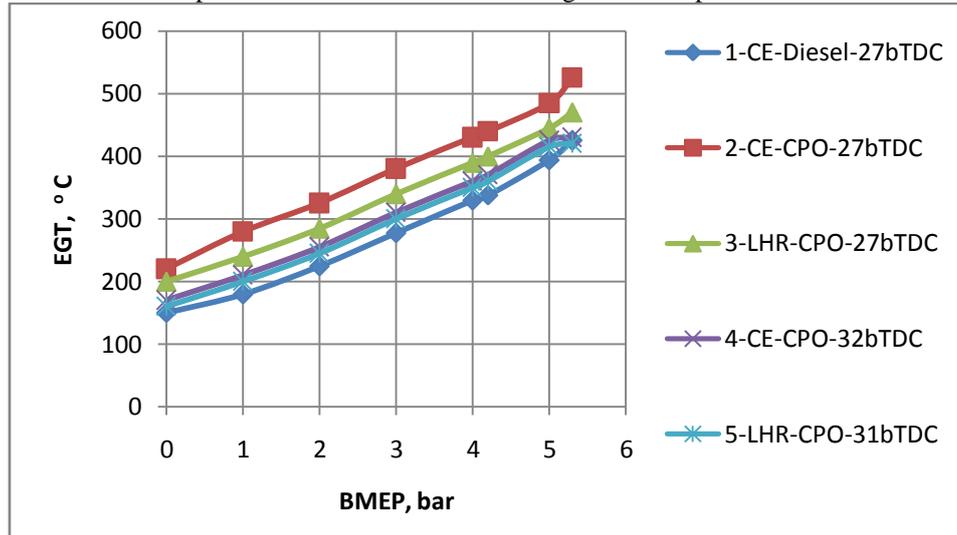

Fig.5 Variation of exhaust gas temperature (EGT) with BMEP in CE and LHR engine at recommend injection timing and optimized injection timings with CPO operation.

This was due to reduction of ignition delay in the hot environment with the provision of the insulation in the LHR engine, which caused the gases expanded in the cylinder giving higher work output and lower heat rejection. This showed that the performance was improved with LHR engine over CE with vegetable oil operation.

The magnitude of EGT at peak load decreased with advancing of injection timing and with increase of injection pressure in both versions of the engine with vegetable oil. Preheating of the vegetable oil further reduced the magnitude of

EGT, compared with normal vegetable oil in both versions of the engine.

Table-2 showed the variation of EGT with injection pressure and injection timing at different operating conditions of CPO with different configurations of the engine. EGT decreased with increase in injection pressure and injection timing with both versions of the engine, which confirmed that performance increased with increase of injection pressure. Preheating of vegetable oil decreased EGT in both versions of the engine.

TABLE-2  
 VARIATION OF EGT AT THE PEAK LOAD WITH THE INJECTION TIMING AND INJECTION PRESSURE IN THE CE AND LHR ENGINE, AT DIFFERENT OPERATING CONDITIONS OF THE VEGETABLE OIL

Fig.6 showed the variation of the volumetric efficiency (VE) with BMEP in CE and LHR engine with CPO at the recommended and optimized injection timings at an injection pressure of 190 bar. VE decreased with an increase of BMEP in both versions of the engine. This was due to increase of gas temperature with the load. At the recommended injection timing, VE in the both versions of the engine with CPO operation decreased at all loads when compared with CE with pure diesel operation. This was due increase of

temperature of incoming charge in the hot environment created with the provision of insulation, causing reduction in the density and hence the quantity of air with LHR engine. VE increased marginally in CE and LHR engine at optimized injection timings when compared with recommended injection timings with CPO. This was due to decrease of un-burnt fuel fraction in the cylinder leading to increase in VE in CE and reduction of gas temperatures with LHR engine.

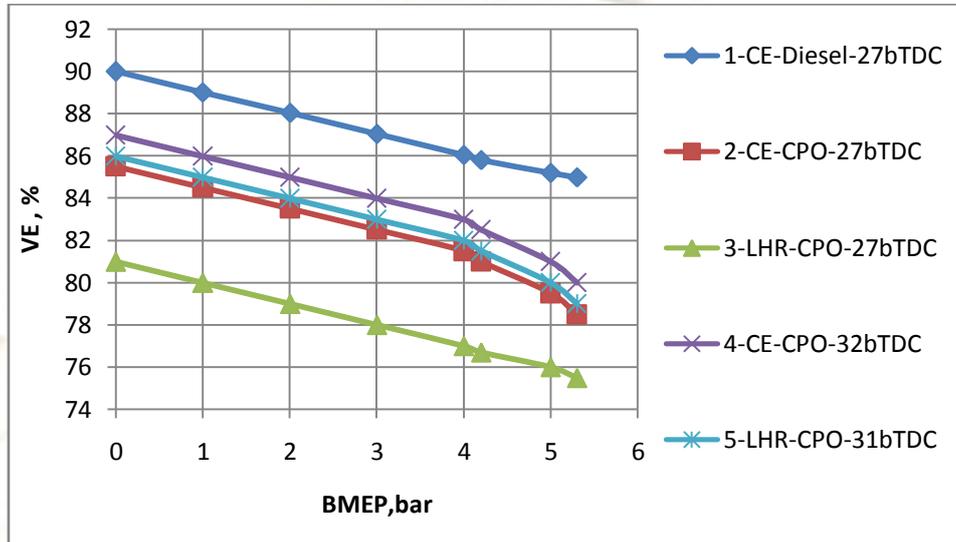

Fig.6. Variation of volumetric efficiency (VE) with BMEP in CE and LHR engine at recommend injection timing and optimized injection timings with CPO operation.

Table-4 showed the variation of VE with injection pressure and injection timing at

different operating conditions of CPO with different configurations of the engine.

TABLE-4

VARIATION OF VOLUMETRIC EFFICIENCY (VE) AT THE PEAK LOAD WITH THE INJECTION TIMING AND INJECTION PRESSURE IN THE CONVENTIONAL AND LHR ENGINES, AT DIFFERENT OPERATING CONDITIONS OF THE VEGETABLE OIL

| Injection timing (°bTDC) | Test Fuel | Volumetric efficiency (%) |      |      |      |      |      |                          |      |      |      |      |      |

| 33                       | DF        | 89                        | --   | 89   | --   | 86   | --   | --                       | --   | --   | --   | --   | --   |

VE increased marginally with the advancing of the injection timing and with the increase of injection pressure in both versions of the engine. This was due to better fuel spray characteristics and evaporation at higher injection pressures leading to marginal increase of VE. This was also due to the reduction of residual fraction of the fuel, with the increase of injection pressure. Preheating of the vegetable oil marginally improved VE in both versions of the engine, because of reduction of un-

burnt fuel concentration with efficient combustion, when compared with the normal temperature of oil.

### B Pollution Levels

Fig.6 showed the variation of the smoke levels with BMEP in CE and LHR engine with vegetable oil operation at the recommended and optimized injection timings at an injection pressure of 190 bar.

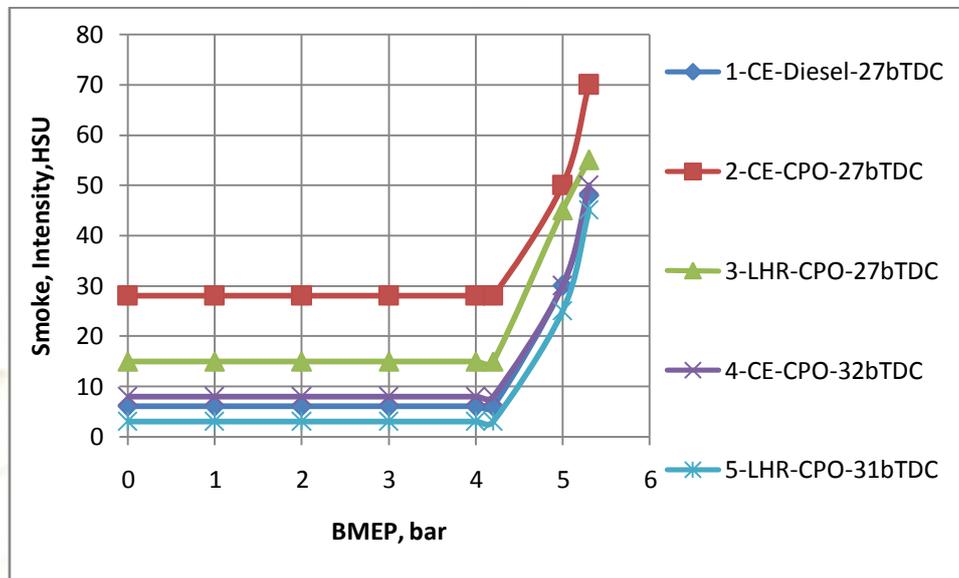

Fig.6. Variation of smoke intensity in Hartridge Smoke Unit (HSU) with BMEP in CE and LHR engine at recommend injection timing and optimized injection timings with crude CPO.

Drastic increase of smoke levels was observed at the peak load operation in CE at different operating conditions of the vegetable oil, compared with pure diesel operation on CE. This was due to the higher magnitude of the ratio of C/H of CPO (1.13) when compared with pure diesel (0.45). The increase of smoke levels was also due to decrease of air-fuel ratios and VE with vegetable oil compared with pure diesel operation. Smoke levels were related to the density of the fuel. Since vegetable oil has higher density compared to diesel fuels, smoke levels are higher with vegetable oil. However, LHR engine marginally reduced smoke levels due to efficient combustion and less amount of fuel accumulation on the hot combustion chamber walls of the LHR engine at different operating conditions of the vegetable oil compared with the CE. Density influences the fuel injection system. Decreasing the fuel density tends to increase spray dispersion and spray penetration. Preheating of the vegetable oils reduced smoke levels in both versions of the engine, when compared with normal temperature of

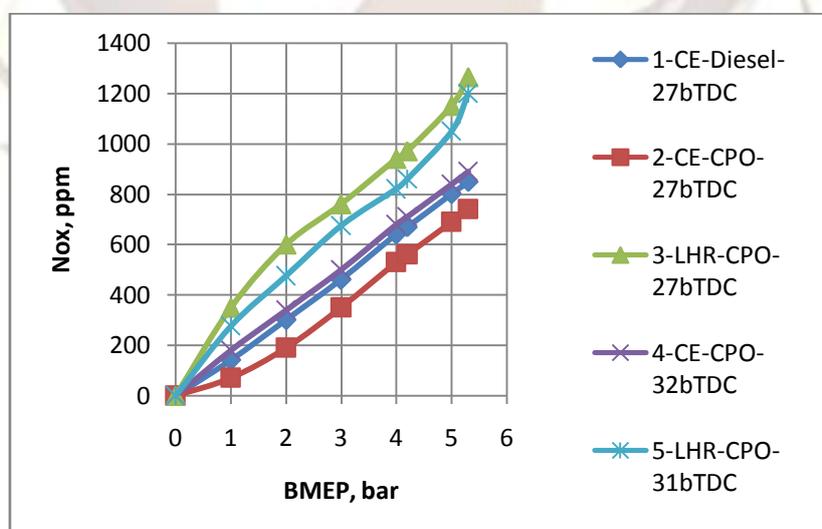

the vegetable oil. This was due to i) the reduction of density of the vegetable oils, as density was directly proportional to smoke levels, ii) the reduction of the diffusion combustion proportion in CE with the preheated vegetable oil, iii) the reduction of the viscosity of the vegetable oil, with which the fuel spray does not impinge on the combustion chamber walls of lower temperatures rather than it directed into the combustion chamber. Table-5 showed the variation of smoke levels with injection pressure and injection timing at different operating conditions of CPO with different configurations of the engine. Smoke levels decreased with increase of injection timings and with increase of injection pressure, in both versions of the engine, with different operating conditions of the vegetable oil. This was due to improvement in the fuel spray characteristics at higher injection pressures and increase of air entrainment, at the advanced injection timings, causing lower smoke levels

Fig.7 showed the variation of the NOx levels with BMEP in CE and LHR engine with vegetable oil at the recommended and optimized injection timings at an injection pressure of 190 bar. NOx levels were lower in CE while they were higher in LHR engine at different operating conditions of the vegetable oil at the peak load when compared with diesel operation. This was due to lower heat release rate because of high duration of combustion causing lower gas temperatures with the vegetable

oil operation on CE, which reduced NOx levels. Increase of combustion temperatures with the faster combustion and improved heat release rates in LHR engine caused higher NOx levels. As expected, preheating of the vegetable oil decreased NOx levels in both versions of the engine when compared with the normal vegetable oil. This was due to improved air fuel ratios and decrease of combustion temperatures leading to decrease NOx emissions in the CE and decrease of combustion temperatures in the LHR engine with the improvement in air-fuel ratios leading to decrease NOx levels in LHR engine.

**Fig.7. Variation of NOx levels with BMEP in CE and LHR engine at recommend injection timing and optimized injection timings with crude CPO operation.**

Table-6 shows the variation of NOx levels with injection pressure and injection timing at different operating conditions of CPO with different configurations of the engine. NOx levels increased with the advancing of the injection timing in CE with different operating conditions of vegetable oil. Residence time and availability of oxygen had increased, when the injection timing was advanced with the vegetable oil operation, which caused higher NOx levels in CE. However, NOx levels decreased with increase of injection pressure in CE. With the increase of injection pressure, fuel

droplets penetrate and find oxygen counterpart easily. Turbulence of the fuel spray increased the spread of the droplets which caused decrease of gas temperatures marginally thus leading to decrease in NOx levels. Marginal decrease of NOx levels was observed in LHR engine, due to decrease of combustion temperatures, which was evident from the fact that thermal efficiency was increased in LHR engine due to the reason sensible gas energy was converted into actual work in LHR engine, when the injection timing was advanced and with increase of injection pressure.

### C Combustion Characteristics

Table-7 presented the comparison on the magnitudes of PP, MRPR, TOPP and TOMRPR with the injection timing and injection pressure, at the peak load operation of CE and LHR engine with vegetable oil operation. Peak pressures were lower in CE while they were higher in LHR engine at the recommended injection timing and pressure, when compared with pure diesel operation on CE. This was due to increase of ignition delay, as vegetable oils require large duration of combustion. Mean while the piston started making downward motion

thus increasing volume when the combustion takes place in CE. LHR engine increased the mass-burning rate of the fuel in the hot environment leading to produce higher peak pressures. The advantage of using LHR engine for vegetable oil was obvious as it could burn low cetane and high viscous fuels. Peak pressures increased with the increase of injection pressure and with the advancing of the injection timing in both versions of the engine, with the vegetable oil operation. Higher injection pressure produced smaller fuel particles with low surface to volume ratio, giving rise to

higher PP. With the advancing of the injection timing to the optimum value with the CE, more amount of the fuel accumulated in the combustion chamber due to increase of ignition delay as the fuel spray found the air at lower pressure and temperature in the combustion chamber. When the fuel- air mixture burns, it produces more combustion temperatures and pressures due to increase of the mass of the fuel. With LHR engine, peak pressures increases due to effective utilization of the charge with the advancing of the injection timing to the optimum value. The magnitude of TOPP decreased with the advancing of the injection timing and with increase of injection pressure in both versions of the engine, at different operating conditions of vegetable oils. TOPP was more with

different operating conditions of vegetable oils in CE, when compared with pure diesel operation on CE. This was due to higher ignition delay with the vegetable oil when compared with pure diesel fuel. This once again established the fact by observing lower peak pressures and higher TOPP, that CE with vegetable oil operation showed the deterioration in the performance when compared with pure diesel operation on CE. Preheating of the vegetable oil showed lower TOPP, compared with vegetable oil at normal temperature. This once again confirmed by observing the lower TOPP and higher PP, the performance of the both versions of the engine improved with the preheated vegetable oil compared with the normal vegetable oil. .

| 32/CPO                              | CE             | 52.3                     | 53.6 |      |      | 3.4                      | 3.6 |     |     | 11                       | 10     |     |    | 0                        | 0      |     |        |

This trend of increase of MRPR and decrease of TOMRPR indicated better and faster energy substitution and utilization by vegetable oils, which could replace 100% diesel fuel. However, these combustion characters were within the limits hence the vegetable oils could be effectively substituted for diesel fuel

### Conclusions

Vegetable oil operation at 27°bTDC on CE showed the deterioration in the performance, while LHR engine showed improved performance, when compared with pure diesel operation on CE. Preheating of the vegetable oils improved performance when compared with normal vegetable oils in both versions of the engine. Improvement in the performance was observed

with the advancing of the injection timing and with the increase of injection pressure with the vegetable oil operation on both versions of the engine. CE with crude vegetable oil operation showed the optimum injection timing at 32°bTDC, while the LHR engine showed the optimum injection at 31°bTDC at an injection pressure of 190 bars. At the recommended injection timing and pressure, crude vegetable oil operation on CE increased smoke levels, decreased NOx levels, while LHR engine decreased smoke levels and increased NOx levels when compared with pure diesel operation on CE. Preheating of the crude vegetable oil decreased smoke levels and NOx levels slightly in both versions of the engine. CE with vegetable oil operation decreased smoke levels and increased NOx levels, while LHR engine decreased smoke

and NO<sub>x</sub> levels with the advancing of the injection timing. With increase in injection pressure, smoke and NO<sub>x</sub> levels decreased in both versions of the engine. Lower peak pressures and more TOPP were observed with normal crude vegetable oil in CE. LHR engine with vegetable oil operation increased PP and decreased TOPP when compared with CE. Preheating increased PP and decreased TOPP when compared with normal vegetable oil operation on both versions of the engine. Lower peak pressures were observed in CE, while higher peak pressures in the LHR engine with crude vegetable oil operation at the recommended injection timing and pressure.
