#### **ABSTRACT**

The concepts of using fibres in order to reinforce matrices weak in tension is more than 4500 years old.since Portland cement concrete started to be used widely as a construction material attempts were made to use fibres for arresting cracks enhance the strength etc. The development of fibre reinforcement for concrete was very slow before 1960's. Fibers are generally used as resistance of cracking and strengthening of concrete. In this project we are going to compare the compressive strength of 3, 7 and 28 days of aramid fibres to the ordinary concrete and fibre reinforced concrete i.e. glass fibres and steel fibres. The concrete is design for M20 grade of concrete. According to various research papers, it has been found that steel fibers give the maximum strength in comparison and glass fibre is used for crack resistance but aramid simultaneously gives strength and can be used for crack resistance. Now a days there exists many reinforcement techniques for improving the strength of those materials which lacks load carrying and less durable capacity. Fiber reinforced concrete has been successfully used in slabs on grade, shotcrete, architectural panels, precast products, offshore structures, structures in seismic regions, thin and thick repairs, crash barriers, footings, hydraulic structures and many other applications. This review study is a trial of giving some highlights for inclusion of aramid fibers especially in terms of using them with new types of concrete.

*Keywords:* Compressive strength, ductility, flexural strength, aramid fibres, Fibre Reinforced Concrete, Split tensile strength, toughness, workability.

#### I. INTRODUCTION

Application of Fibre Reinforced Concrete is continuously growing in various application fields. FRC is widely used in structures. Due to the property that fibre enhances toughness of concrete, FRC is used on large scale for structural purposes. The fibre is described by a convenient parameter called aspect ratio. The aspect ratio of the fiber is the ratio of its length to its diameter. The principle motive behind incorporating fibers into a cement matrix is to increase the toughness and strength and improve the deformation characteristics the resultant composite. For FRC to be a valuable construction material, it must be able to compete economically with existing reinforcing system. FRC composite properties, such as crack resistance, reinforcement and increase in toughness are dependent on the mechanical properties of the fiber, bonding properties of the fiber and matrix, as well as the quantity and distribution within the matrix of the fibers. It improves fatigue resistance makes crack pattern distributed. By making crack pattern distributed, it is meant that it decreases the crack width. Aramid fibre gives more compressive strength and crack resistance to concrete as compare to glass and steel fibre.

# II. MATERIALS

| i.   | Cement         | Pozzolana Portland       |
|------|----------------|--------------------------|
|      |                | cement of [53 grade]     |
| ii.  | Coarse         | Size 20mm                |
|      | aggregate      |                          |
| iii. | Fine aggregate | Size 10mm                |
| iv.  | Sand           | Less than 4.75mm         |
| v.   | Admixture      | Super plasticizers       |
| vi.  | Fibres         | Glass fibre, steel fibre |
|      |                | and Aramid fibre.        |
| vii. | Water          | Potable water            |

#### III. METHODOLOGY

Concrete ingredients are firstly collected from various locations. As per IS specification material is tested i.e. test which are usually performed to check the material's physical properties. The proportioning of quantity of cement, materials like fine aggregate, coarse aggregate and fibres like Glass fibre, Steel fiber and Aramid fibre has been done by weight as per the mix design . Water, super plasticizer were measured by volume. Concrete was design for M20 grade as per IS 456-2000 and IS 10262.

The mixing process is carried out in concrete mixture. The materials are laid in uniform layers, one on the other in order – fine aggregate, coarse aggregate and fibres as per the percentage like 0.3%, 0.5% and 0.7% respectively. Dry mixing

Is done, then cement is added and in last water is added. Fresh concrete is tested to check the slump of concrete, as addition of different percentage of fibres may change the slump of concrete, then concrete is

filled in empty moulds and kept for 24 hours. After 24 hours cubes are de-mould and placed in curing tank for curing. After that compressive testing was done after 3, 7, and 28 days of curing.

## IV. RESULT

Results for M-20 Grade of Concrete in Compression Test of 3, 7 And 28 Days

## **ORDINARY CONCRETE**

| M20 PCC |          |          |                  |  |  |

#### V. CONCLUSION

For glass and steel reinforcement, strength of concrete increased with, increased in fibre dosage up to 0.5 % as compared to glass fibre, aramid fibre gives 48% more compressive strength, whereas when comparing aramid and steel fibre, aramid gives 66% increased compressive strength.

Aramid reinforced concrete produce massive compressive strength as here, the aramid reinforced concrete is introducing compressive strength as equal to M35 grade in design of M20 grade.
